Density functional theory (DFT) calculations are widely used to characterize the electronic structure and magnetic resonance parameters of paramagnetic molecules. Here we address the versatility of plane-wave DFT for studying impurities in solids in combination with pulsed EPR techniques. We focus on hydroxyapatite $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$ (nano)crystals as a host lattice, since it is very tolerant to many ionic substitutions. We show that the calculation of magnetic resonance parameters in conjunction with EPR/ENDOR experiment can successfully complement first-principles thermodynamic analyses of the impurity localization. Next, we attempt to connect the results of electron spin-lattice relaxation measurements with the calculated phonon properties of the host crystal. Finally, we illustrate the capabilities of the combined experimental-computational approach for studying the interplay of oppositely charged substitution in the structure of hydroxyapatite nanopowders.
