
Dear Author,

Please correct your galley proofs carefully and return them no more than four days after the page proofs have been received.

The editors reserve the right to publish your article without your corrections if the proofs do not arrive in time.

Note that the author is liable for damages arising from incorrect statements, including misprints.

Please note any queries that require your attention. These are indicated with a Q in the PDF and a question at the end of the document.

Please limit corrections to errors already in the text; cost incurred for any further changes or additions will be charged to the author, unless such changes have been agreed upon by the editor.

Reprints may be ordered by filling out the accompanying form.

Return the reprint order form by fax or by e-mail with the corrected proofs, to Wiley-VCH : pss.rapid@wiley-vch.de

To avoid commonly occurring errors, please ensure that the following important items are correct in your proofs (please note that once your article is published online, no further corrections can be made):

- **Names** of all authors present and spelled correctly
- **Titles** of authors correct (Prof. or Dr. only: please note, Prof. Dr. is not used in the journals)
- **Addresses** and **postcodes** correct
- **E-mail address** of corresponding author correct (current email address)
- **Funding bodies** included and grant numbers accurate
- **Title** of article OK
- All **figures** included
- **Equations** correct (symbols and sub/superscripts)

Corrections should be made directly in the PDF file using the PDF annotation tools. If you have questions about this, please contact the editorial office. The corrected PDF and any accompanying files should be uploaded to the journal's Editorial Manager site.

UNCORRECTED PROOF

Self-Consistent Four-Particle Cluster Model of Fe³⁺ Heisenberg Chains: Spectral and Magnetic Properties of YFe₃(BO₃)₄ Crystals

Boris Z. Malkin, Elena A. Popova, Elena P. Chukalina, Artjoms Jablunovskis, and Marina N. Popova*

The magnetic properties of antiferromagnetic quasi-1D YFe₃(BO₃)₄ crystals are studied based on the analysis of the measured optical spectra of the Fe³⁺ ions in different rare-Earth (RE) iron borates and a self-consistent four-particle cluster approach to helical iron chains. The parameters of crystal fields affecting the Fe³⁺ ions are calculated in the framework of the exchange charge model. The parameters of the isotropic intrachain and interchain exchange interactions between the Fe³⁺ ions are determined from modeling the temperature dependences of magnetic susceptibilities, the phase transition temperature, and spontaneous magnetic moments. The magnetic easy-plane anisotropy is explained as the result of dipolar interactions between the Fe³⁺ ions in the trigonal crystal lattice. The developed model can be used to analyze and predict the properties of multiferroic multifunctional RE iron borates and highlight contributions of the iron subsystem into the magnetoelectric and magnetoelastic effects in these compounds.

Multiferroic rare-earth (RE) iron borates REFe₃(BO₃)₄ attract attention of researchers because of interesting magnetic, magnetoelectric, magnetoelastic,^[1–3] magnetodielectric,^[4] and optical properties,^[5–8] some of which have an application potential. To completely realize this potential, it is necessary to build physically grounded models of different interactions in iron borates, which would allow one to correctly simulate magnetic, multiferroic, and optical properties of these compounds and develop the

microscopic theory of the ME effect and other phenomena. The most significant structural feature of RE iron borates is the helical chains of FeO₆ octahedra.^[6,9,10] This quasi-1D of the Fe magnetic subsystem is responsible, in particular, for relatively low Neel temperatures as compared with the energy of intrachain exchange interactions and for short-range correlations observed in RE iron borates at temperatures well above T_N .^[11,12] In this Letter, we present a minimal model that quantitatively describes the physical properties of high-spin chains with different space structures (linear, zig-zag, or helical). The main idea is that using the exact diagonalization method and expanding the Bethe–Peierls approximation,^[13] to clusters containing at least one internal pair of particles coupled with antiferromagnetic exchange interaction (i.e., at least two dimers), we can accurately take into account spin correlations of nearest neighbors. In particular, the essential drawbacks of previously used self-consistent single-site or dimer models in studies of RE iron borates, namely, a presence of a magnetic order in an isolated chain and strongly overestimated values of the exchange integrals and Neel temperatures,^[14] are removed in the present work. To test the model, we choose the YFe₃(BO₃)₄ crystal containing only one magnetic system, namely, just the iron one.

YFe₃(BO₃)₄ crystals belong to the trigonal sp gr $P3_121$ at temperatures below 360 K.^[10] The unit cell in the paramagnetic phase contains two types of structurally nonequivalent Fe³⁺ ions (Fe1 and Fe2 ions in the 3a and 6c positions, respectively, see Figure 1a), forming helical Fe1 and Fe2 chains along the *c*-axis. The lattice constants are $a = 0.95161$ nm and $c = 0.75441$ nm.^[15] The Fe2 chains are shifted by ± 0.0088 nm along the *c*-axis from the *ab* planes containing the Fe1 and Y ions. Iron ions are sixfold coordinated by oxygen ions forming strongly deformed edge-sharing octahedra, the point symmetry groups are C_2 and C_1 at Fe1 and Fe2 sites, respectively. The R_{nn} distances between the nearest-neighbor iron ions in the chains are ≈ 0.315 nm; the next-nearest neighbors of Fe1 ions at a distance $R_{n+2n} \approx 0.435$ nm are two Fe2 ions belonging to different Fe2 chains. The second neighbors of Fe2 ions are one Fe1 ion and one Fe2 ion.

Optical transitions of iron ions in REFe₃(BO₃)₄ lead to wide absorption bands which are practically independent of the

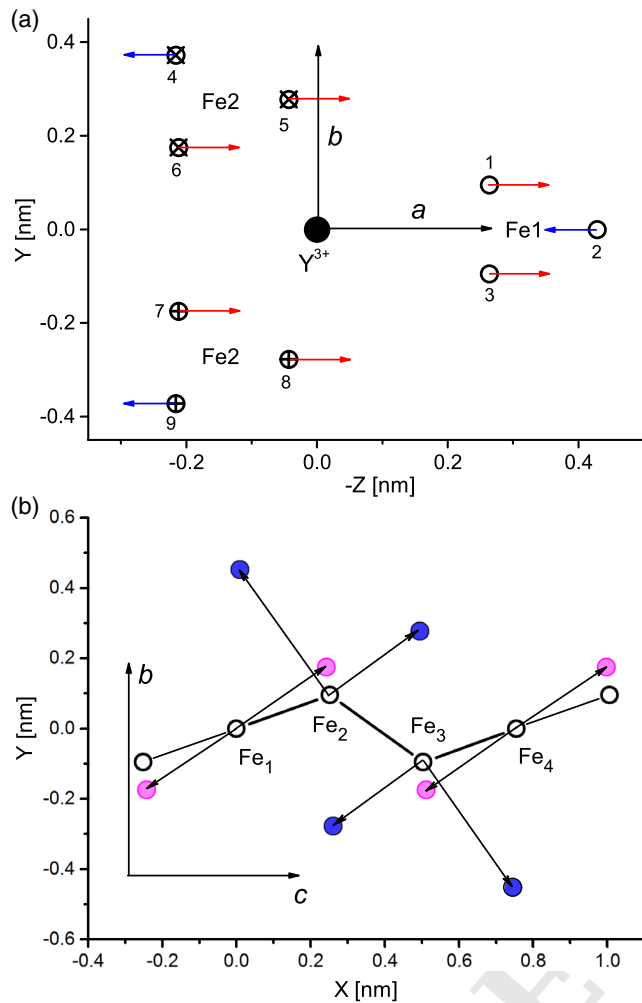

Figure 1. Projection of a) Fe1 (empty circles), Fe2 (circles with a cross), and yttrium (big black circle) ions in a unit cell of $\text{YFe}_3(\text{BO}_3)_4$ onto the ab plane. Magnetic moments at temperatures $T < T_N$ are shown by arrows. b) a Fe1 chain (empty circles) and the nearest-neighbor Fe2 ions (filled circles) from six different chains onto the cb plane. The global coordinate system is used with the axes $x \parallel c$, $y \parallel b$, $z \parallel -a$.

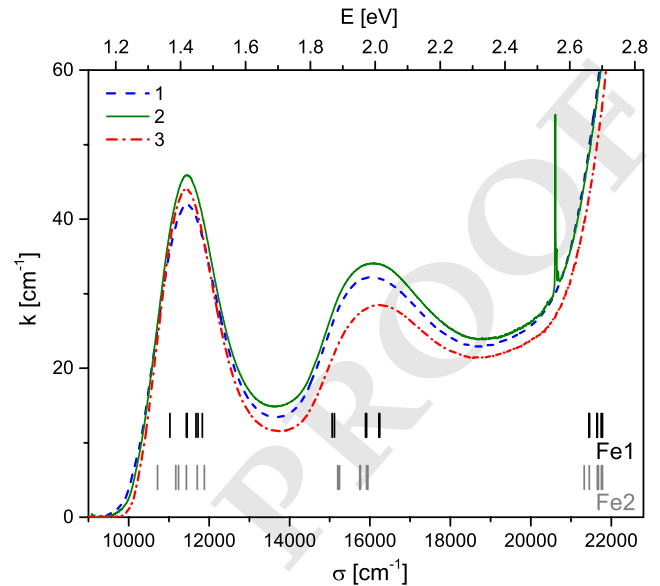

Figure 2. Absorption spectra of $\text{YFe}_3(\text{BO}_3)_4$ (1), $\text{TbFe}_3(\text{BO}_3)_4$ (2), and $\text{GdFe}_3(\text{BO}_3)_4$ (3) measured at 100 K and calculated wave numbers (sticks) of zero-phonon transitions in Fe^{3+} ions. A narrow line at about $20\,600\text{ cm}^{-1}$ in 2 is due to transitions of the Tb^{3+} ions in $\text{TbFe}_3(\text{BO}_3)_4$.

calculations agree satisfactorily with the observed three broad 1
2

The ground state ${}^6S_{5/2}$ is split by CF and spin-orbit interactions 3
4 into three Kramers doublets, but the total splitting is rather small, less than 2 cm^{-1} . For both the lowest doublets of the Fe1 5
6 and Fe2 ions, the g factor corresponding to the magnetic field direction along or close to the c -axis is about 10, but other two 7
8 principal values of the g tensor are less than 0.2. Neglecting these small values, we get Ising-type doublets. The calculated magnetic 9
10 susceptibilities of isolated Fe1 and Fe2 ions at temperatures below 5 K are strongly anisotropic (Figure S1, Supporting 11
12 Information). However, as shown later, this single-ion easy-axis anisotropy, as well as the possible charge transfer effects,^[18] 13
14 is suppressed by strong isotropic exchange interactions.

The Hamiltonian of a cluster $\text{Fe}_1\text{—Fe}_2\text{—Fe}_3\text{—Fe}_4$ (see 15
16 Figure 1b) in the space of 6^4 states corresponding to the ground multiplet ${}^6S_{5/2}$ of iron ions in the CF 17

$$H_{\text{Cl}} = H_{\text{Cl}}^{(0)} + H_{\text{ex}} + H_Z + H'_{\text{ex}} \quad (1) \quad \begin{matrix} \text{Q9} \\ \text{Q10} \end{matrix}$$

includes the sum of energies of noninteracting ions $H_{\text{Cl}}^{(0)}$, exchange 18
19 interactions inside the cluster $H_{\text{ex}} = -2J_1(\mathbf{S}_1\mathbf{S}_2 + \mathbf{S}_2\mathbf{S}_3 + \mathbf{S}_3\mathbf{S}_4)$, the Zeeman energy $H_Z = -(\mathbf{M}_1 + \mathbf{M}_2 + \mathbf{M}_3 + \mathbf{M}_4)\mathbf{B}$ in an 20
21 external magnetic field \mathbf{B} , and exchange interactions with the neighboring ions (with spin operators \mathbf{S}') in the same chain and 22
23 in six neighboring chains

$$H'_{\text{ex}} = -2J_1(\mathbf{S}_1\mathbf{S}'_1 + \mathbf{S}_4\mathbf{S}'_4) - 2J_2 \sum_{k=1,2,3,4} \mathbf{S}_k(\mathbf{S}'_{k,1} + \mathbf{S}'_{k,2}) \quad (2)$$

The matrices \mathbf{M}_p and \mathbf{S}_p represent the projections of operators 24
25 of the magnetic and spin moments of the p -th iron ion onto the space of wave functions of the ground multiplet sublevels in 26

1 specific RE ion (see Figure 2). Experimental details can be found 2
3 in Supporting Information. We use the measured spectra to verify the results (described in 4
5 Supporting Information) of crystal-field (CF) calculations,^[16,17] for the Fe1 and Fe2 ions, which are the first steps in developing 6
7 a four-particle cluster model for the Fe^{3+} Heisenberg chain. Two independent sets of the calculated CF parameters for the Fe1 and 8
9 Fe2 ions are given in Supporting Information (Table S1, Supporting Information). These CF parameters were used to calcu- 10
11 late energies of states originating from the ground (6S) and low-energy Fe^{3+} free-ion terms (4G , 4P , 4D , 2I), and they are 12
13 listed in Supporting Information (Table S2, Supporting Information). Frequencies of spin-allowed ($\Delta S = 1$) zero-phonon 14
15 radiative transitions of iron ions are shown by sticks in Figure 2. Having in mind possible Stokes shifts of electron-vibrational 16
17 bands in the absorption spectra from zero-phonon lines to higher frequencies of up to 10^3 cm^{-1} , we argue that the results of

1 the CF. To reduce the number of variable model parameters, we
2 neglect possible differences in the exchange integrals in the Fe1
3 and Fe2 chains. Spin operators are related to magnetic moment
4 operators by the relations $\mathbf{S}_p = \mathbf{g}_p^{-1} \mathbf{M}_p / \mu_B$ (μ_B is the Bohr mag-
5 neton). Below, we neglect small differences (not exceeding
6 2×10^{-3}) between the calculated matrices $M_{p,\alpha} / \mu_B$ and $2S_{p,\alpha}$,
7 $g_{p,\alpha\beta} = g\delta_{\alpha\beta}$ ($\alpha, \beta = x, y, z$), $g = 2$.
8 The effective Hamiltonian of a cluster in the paramagnetic
9 phase can be written as

$$H_{Cl,eff} = H_{Cl}^{(0)} + H_{ex} - (\mathbf{M}_1 + \mathbf{M}_4) \mathbf{B}_{loc}^{(o)} - (\mathbf{M}_2 + \mathbf{M}_3) \mathbf{B}_{loc}^{(i)} \quad (3)$$

10 where $\mathbf{B}_{loc}^{(\lambda)}$ are magnetic fields affecting the pairs of inner ($\lambda = i$)
11 and outer ($\lambda = o$) iron ions in the cluster, respectively. We deter-
12 mine the local susceptibilities $\kappa_{\alpha\beta}^{(\lambda\lambda')}$ of iron ions through the
13 responses of their average magnetic moments to local fields $\mathbf{B}_{loc}^{(\lambda)}$

$$\langle M_{\alpha}^{(\lambda)} \rangle = \sum_{\beta\lambda'} \kappa_{\alpha\beta}^{(\lambda\lambda')} B_{loc,\beta}^{(\lambda')} \quad (4)$$

14 where $\mathbf{M}^{(i)} = (\mathbf{M}_2 + \mathbf{M}_3)/2$, $\mathbf{M}^{(o)} = (\mathbf{M}_1 + \mathbf{M}_4)/2$, and

$$\kappa_{\alpha\beta}^{(\lambda\lambda')} = \lim_{h \rightarrow 0} \text{Tr}[M_{\alpha}^{(\lambda)} \rho(H_{Cl}^{(0)} + H_{ex} - 2M_{\beta}^{(\lambda')} h) / h] \quad (5)$$

15 Here, $\rho(H)$ is the equilibrium density matrix of the system
16 with the Hamiltonian H . The calculated local susceptibilities
17 in the range of temperature $T > T_N = 38$ K are shown in
18 Supporting Information (Figure S2, Supporting Information).
19 The isotropic exchange interaction substantially suppresses the
20 off-diagonal components of the single-ion susceptibility tensors
21 (see Figure S1 and S2, Supporting Information), which we
22 neglect below.

23 Furthermore, following the self-consistent field approxima-
24 tion, we replace operators of the spin and magnetic moments
25 of iron ions surrounding the selected cluster by their average
26 values. We obtain the following expressions for local fields where
27 auxiliary magnetic fields $\Delta\mathbf{B}(\text{Fek})$ acting on the outer ions of a
28 cluster are added,^[13] ($J'_p = J_p / (g\mu_B)^2$, $p = 1, 2$)

$$\mathbf{B}_{loc}^{(o)}(\text{Fe1}) = \mathbf{B} + [2J'_1 \langle \mathbf{M}(\text{Fe1}) \rangle + 4J'_2 \langle \mathbf{M}(\text{Fe2}) \rangle] + \Delta\mathbf{B}(\text{Fe1}) \quad (6)$$

$$\mathbf{B}_{loc}^{(o)}(\text{Fe2}) = \mathbf{B} + 2[J'_1 \langle \mathbf{M}(\text{Fe2}) \rangle + J'_2 (\langle \mathbf{M}(\text{Fe1}) \rangle + \langle \mathbf{M}(\text{Fe2}) \rangle)] + \Delta\mathbf{B}(\text{Fe2}) \quad (7)$$

$$\mathbf{B}_{loc}^{(i)}(\text{Fe1}) = \mathbf{B} + 4J'_2 \langle \mathbf{M}(\text{Fe2}) \rangle,$$

$$\mathbf{B}_{loc}^{(i)}(\text{Fe2}) = \mathbf{B} + 2J'_2 [\langle \mathbf{M}(\text{Fe1}) \rangle + \langle \mathbf{M}(\text{Fe2}) \rangle] \quad (8)$$

$$\mathbf{B}_{loc}^{(i)}(\text{Fe2}) = \mathbf{B} + 2J'_2 [\langle \mathbf{M}(\text{Fe1}) \rangle + \langle \mathbf{M}(\text{Fe2}) \rangle]$$

29 These fields are determined from the condition imposed on
30 the average magnetic moments

$$\langle \mathbf{M}^{(o)} \rangle = \langle \mathbf{M}^{(i)} \rangle = \langle \mathbf{M}(\text{Fek}) \rangle = \chi(\text{Fek}) \mathbf{B} \quad (9)$$

31 where $\chi(\text{Fek})$ is the magnetic susceptibility of the ions
32 Fek ($k = 1, 2$). Substituting Equation (6)–(8) into Equation (4),
33 we obtain a coupled system of equations for $\langle \mathbf{M}(\text{Fek}) \rangle$

$$\langle \mathbf{M}(\text{Fe1}) \rangle = \chi_0(\text{Fe1}) [\mathbf{B} + 4J'_2 \langle \mathbf{M}(\text{Fe2}) \rangle] \quad (10)$$

$$\langle \mathbf{M}(\text{Fe2}) \rangle = \chi_0(\text{Fe2}) [\mathbf{B} + 2J'_2 (\langle \mathbf{M}(\text{Fe1}) \rangle + \langle \mathbf{M}(\text{Fe2}) \rangle)] \quad (11)$$

where $\chi_0(\text{Fek}) = (\kappa^{(ii)} \kappa^{(oo)} - \kappa^{(io)2}) / (\kappa^{(oo)} - \kappa^{(io)})$. Its solution
gives the susceptibilities $\chi(\text{Fek})$ (see Equation S2–S4,
Supporting Information). From a comparison of the calculated
susceptibilities $\chi = \chi(\text{Fe1}) + 2\chi(\text{Fe2})$ with the measurement
data^[19] ($\chi_{\parallel} = \chi_{cc}$, $\chi_{\perp} = (\chi_{aa} + \chi_{bb})/2$), we obtained the exchange
integrals $J_1 = -5.5$ K and $J_2 = -3.45$ K. It should be noted that
neglecting the quantum fluctuations of the magnetic moments
(replacing the spin operators by their average values) leads to sig-
nificantly higher values of the exchange integrals compared with
actual values to reproduce the measured susceptibility. The mat-
ter is that the increased antiferromagnetic exchange interaction
compensates for the reduction in the magnetic moment due to
fluctuations.

In the antiferromagnetic phase, the magnetic moments of
neighboring ions in helical chains are antiparallel, $\mathbf{M}_1 = -\mathbf{M}_2 =$
 $\mathbf{M}_3 = -\mathbf{M}_4$. As follows from the measurement data,^[20] and the
results of the calculation of magnetic anisotropy (see below),
the magnetic moments of iron ions in the antiferromagnetic
phase are perpendicular to the c -axis. The most natural assump-
tion is that they are aligned along one of the three C_2 axes.
(The problem of calculating the sixth-order anisotropy constant,
which is determined in the case of a trigonal system by magne-
toelastic interaction, is beyond the scope of this Letter.) At the
phase-transition temperature T_N , the response of the system
to a spatially inhomogeneous magnetic field (staggered field \mathbf{B}_s),
the direction of which at the positions of the iron ions coincides
with the directions of their magnetic moments, diverges. The
calculation of this response, i.e., of the antiferromagnetic suscep-
tibility, is carried out similarly to the above derivation of the
expression for paramagnetic susceptibility by considering a four-
particle cluster in a chain subjected to a staggered field \mathbf{B}_s
(for details, see Supporting Information). The antiferromagnetic
susceptibilities of the subsystems of ions Fe1 and Fe2 are
obtained in the form

$$\chi_s(\text{Fek}) = \chi_{0s}(\text{Fek}) \{1 + 2J'_{2R} [\chi_{0s}(\text{Fe1}) + \chi_{0s}(\text{Fe2}) - \chi_{0s}(\text{Fek})]\} / \Delta_s \quad (12)$$

Here, $\Delta_s = 1 + 2J'_{2R} \chi_{0s}(\text{Fe2}) - 8J'_{2R}{}^2 \chi_{0s}(\text{Fe1}) \chi_{0s}(\text{Fe2})$ and $\chi_{0s} =$
 $(\kappa_s^{(ii)} \kappa_s^{(oo)} - \kappa_s^{(io)2}) / (\kappa_s^{(oo)} - \kappa_s^{(io)})$, where $\kappa_s^{(\lambda\lambda')}$ are local susceptibil-
ities defined by Equation (5) for the corresponding chains in the
staggered field \mathbf{B}_s . Note that, when considering the intercluster
interactions in the antiferromagnetic phase, we introduce renor-
malized exchange integrals $J_{pR} = R_p J_p$ ($p = 1, 2$), where R_p is the
reduction factor. The expression for the denominator Δ_s in
Equation (12) demonstrates the formation of a long-range order,
explicitly, due to the exchange interchain interaction (with the
exchange integral J_{2R}) and, indirectly, due to exchange interac-
tions in the chains which determine the temperature dependen-
ce of the susceptibilities of isolated clusters $\chi_{0s}(\text{Fek})$. The
transition temperature satisfies the equation

$$\chi_s(T_N)^{-1} = [\chi_s(\text{Fe1}, T_N) + 2\chi_s(\text{Fe2}, T_N)]^{-1} = 0 \quad (13)$$

Additional restrictions on the magnitude of the exchange inte-
grals J_{pR} are obtained from the consideration of the spontaneous

1 magnetic moments of iron ions. The spontaneous moments are
2 determined by the system of coupled self-consistent equations

$$M_s(\text{Fek}) = \langle M_{1a} \rangle = \langle M_{3a} \rangle = -\langle M_{2a} \rangle = -\langle M_{4a} \rangle$$

$$= \text{Tr}[M_{1a}\rho(H_{\text{Cl,af}}(\text{Fek}))] \quad (14)$$

3 where $H_{\text{Cl,af}}(\text{Fek})$ is the effective cluster Hamiltonian in the anti-
4 ferromagnetic phase in zero external field. The temperature
5 dependence of the average magnetic moment $M = [M_s(\text{Fe1})$
6 $+ 2M_s(\text{Fe2})]/3$ calculated in accordance with Equation (14) at
7 the reduction coefficients $R_1 = 0.463$ and $R_2 = 0.264$ agrees
8 satisfactorily with the data of neutron diffraction measure-
9 ments^[20] (see Figure S3, Supporting Information). When used
10 in the calculations, the reduction factors presented earlier,
11 the solution $T_N = 38$ K of Equation (13) coincides with the
12 measurement data (see Supporting Information and Figure S5
13 therein).

14 In the case of S-state ions, magnetic dipolar interactions play a
15 dominant role in the formation of magnetic anisotropy. We con-
16 sidered the contribution of the dipolar interactions to the energy
17 of the iron subsystem in $\text{YFe}_3(\text{BO}_3)_4$ as a function of an angle θ
18 between the c -axis and the iron magnetic moments \mathbf{M}_{Fek} , assum-
19 ing a collinear antiferromagnetic structure formed by the parallel
20 magnetic moments of ions lying in (Fe1 ions in the sublattice 2
21 with moments \mathbf{M}_{Fe1}) or close to (Fe2 ions with moments \mathbf{M}_{Fe2} in
22 sublattices 4 and 9, see Figure 1a) a fixed ab plane and antiparallel
23 to moments of ions in neighboring ab planes shifted along the
24 c -axis by $\pm c/3$ (sublattices 1, 6, 8 and 3, 5, 7). The sums over
25 the crystal lattice with the unit cell of $\text{YFe}_3(\text{BO}_3)_4$ doubled along
26 the c -axis were calculated using the Ewald method. The obtained
27 energy of the magnetic subsystem in the assumed antiferro-
28 magnetic structure with $\mathbf{M}_{\text{Fek}} = \mathbf{M}$ equals

$$E = [2(J_{1R} + J_{2R})/\mu_B^2] - \frac{138.1\pi}{27\nu}(1 - 3\cos^2\theta)M^2 \quad (15)$$

29 where $\nu = \sqrt{3}a^2c$ is the unit-cell volume. Substituting the numeri-
30 cal values of the parameters into Equation (15), we obtain
31 $E = [-8.29 - 0.0085(1 - 3\cos^2\theta)](M/\mu_B)^2$ in degrees Kelvin.
32 As shown, the energy of magnetic anisotropy is three orders of
33 magnitude lower than the energy of exchange interactions.
34 Dipole-dipole interactions practically do not affect the tempera-
35 ture of phase transition, but they determine the easy-plane type
36 of the magnetic structure. The energy of the magnetic subsystem
37 is minimal when the magnetic moments are oriented in a plane
38 perpendicular to the c -axis. An estimate of the magnetic anisotropy
39 field H_A parallel to the c -axis, in which the Zeeman energy
40 compensates for the increase in the energy of iron ions when
41 the magnetic moment $M \approx 4\mu_B$ rotates from the plane to the
42 c -axis, yields $H_A = 1.51$ kOe, which is close to that found from
43 the measurements of the antiferromagnetic resonance spectra
44 at $T = 4.2$ K (1.44 kOe).^[21]

45 In the magnetically ordered phase, induced by an external
46 magnetic field, changes of magnetic moments of inner and outer
47 iron ions in a cluster can be written similarly to Equation (4) with
48 the local susceptibilities defined by the expression

$$\kappa_{\alpha\beta}^{(\lambda\lambda')} = \lim_{h \rightarrow 0} \text{Tr}\{M_{\alpha}^{(\lambda)}[\rho(H_{\text{Cl,af}} - 2M_{\beta}^{(\lambda')}h) - \rho(H_{\text{Cl,af}})]/h\} \quad (16)$$

The local magnetic fields can be written similarly to
Equation (6)–(8) where it is enough to replace J_1, J_2 and $\mathbf{M}(\text{Fek})$
by J_{1R}, J_{2R} , and $\Delta\mathbf{M}(\text{Fek})$, respectively. The auxiliary fields
 $\Delta\mathbf{B}(\text{Fek})$ and the effective single-ion susceptibilities $\chi(\text{Fek})$ are
determined by the condition of equivalence of iron ions with dif-
ferent directions of spontaneous moments in weak external
fields: $\langle \Delta\mathbf{M}^{(o)} \rangle = \langle \Delta\mathbf{M}^{(i)} \rangle = \langle \Delta\mathbf{M}(\text{Fek}) \rangle = \chi(\text{Fek})\mathbf{B}$. The
temperature dependences of the local susceptibilities $\kappa_{\alpha\beta}^{(\lambda\lambda')}$ at
temperatures $T < T_N$ are shown in Figure S2, Supporting
Information. The antiferromagnetic exchange interaction sup-
presses single-ion magnetic anisotropy, the off-diagonal compo-
nents of the susceptibility tensor take values smaller than the
diagonal components by three orders of magnitude.

The calculation results on the components of the magnetic
susceptibility tensor of a $\text{YFe}_3(\text{BO}_3)_4$ crystal in the paramagnetic
and antiferromagnetic phases are compared with the measure-
ment data^[19] in Figure 3. The susceptibility in the antiferro-
magnetic phase in magnetic fields perpendicular to the c -axis,
 $\chi_{\perp} = (\chi_{aa} + \chi_{bb})/2$, is obtained by averaging over three possible
domains with orientations of magnetic moments along the three
 C_2 axes. Figure 3 shows a good agreement between the calculated
and measured susceptibilities in both the paramagnetic and
antiferromagnetic phases. In particular, the nonmonotonous
behavior of the low-temperature ($T < T_N$) susceptibility, $\chi_{\parallel} = \chi_{cc}$,
which was also observed for the easy-plane antiferromagnets
 $\text{EuFe}_3(\text{BO}_3)_4$ and $\text{SmFe}_3(\text{BO}_3)_4$,^[1] with the dominant contribu-
tions of the iron subsystem to susceptibility, is reproduced by
the presented model.

A model of four-particle self-consistent clusters in helical iron
chains is developed, which can be used for the physically
grounded modeling of various properties of functional RE iron
borates, taking into account the quasi-1D of the iron sub-
system. This model was tested by simulating the properties of
 $\text{YFe}_3(\text{BO}_3)_4$ crystals containing only the iron magnetic system.
The parameters of CFs acting on the Fe^{3+} ions and the energy
spectra of the $3d^5$ electronic shell of Fe^{3+} in $\text{YFe}_3(\text{BO}_3)_4$ were
calculated. The obtained frequencies of spin-allowed zero-phonon

Figure 3. Temperature dependences of the components of the magnetic susceptibility tensor for $\text{YFe}_3(\text{BO}_3)_4$. Black dotted lines are the results of calculations, blue solid and red dash-dotted lines are the measurement data.^[19]

1 radiative transitions in iron ions correlate satisfactorily with
2 the measured absorption spectra of different RE iron borates.
3 Then, presented earlier in the literature, temperature dependen-
4 ces of components of the magnetic susceptibility tensor of
5 $\text{YFe}_3(\text{BO}_3)_4$ in both the paramagnetic and antiferromagnetic
6 phases were successfully simulated using the developed four-
7 particle cluster model. A good agreement between the experi-
8 mental and calculated data testifies a good quality of the model.
9 The model can be used to analyze properties of the entire family
10 of multifunctional RE iron borates and highlight the contribution
11 of the iron subsystem into these properties.

Information regarding VAT: Please note that from German sales tax point of view, the charge for Reprints, Issues or Posters is considered as “supply of goods” and therefore, in general, such delivery is a subject to German sales tax. However, this regulation has no impact on customers located outside of the European Union. Deliveries to customers outside the Community are automatically tax-exempt. Deliveries within the Community to institutional customers outside of Germany are exempted from the German tax (VAT) only if the customer provides the supplier with his/her VAT number. The VAT number (value added tax identification number) is a tax registration number used in the countries of the European Union to identify corporate entities doing business there. Starting with a country code (e.g. FR for France), followed by numbers.
